Abstract

The objective of this paper was to compare the performance of two algorithms, the Suffix Automaton and the Enhanced Suffix Array, for solving the Longest Common Substring problem in a pure Python implementation.

The algorithms were tested on multiple scenarios, from best case to worst case, and on multiple string lengths, from 100 to 10,000 characters, with multiple runs for each scenario and string length to ensure statistical significance of the results. Both the build time and the query time were measured, as well as the memory used both for building the data structure and for querying it.

The results showed that **so long as one is programming in pure Python**, an Enhanced Suffix Array offers practically zero advantages over a Suffix Automaton. The Suffix Automaton was substantially faster to build and to query in all but one scenario, and although the Enhanced Suffix Array had an overall smaller index size, this would do very little in real-life memory-constrained applications, as its peak memory usage was either comparable to the Suffix Automaton or only barely smaller in all scenarios and string lengths.

This is potentially due to the nature of Python, as it is a high level interpreted language where the memory management is abstracted away from the programmer, leading to even simple data types like integers and lists having a much higher memory overhead than in lower level languages like C. Due to Python's memory management, the Enhanced Suffix Array would also lose its cache locality, which is the main reason for its compactness in lower level languages like C.

Abstrakt

Das Ziel dieser Arbeit war es, die Leistung von zwei Algorithmen, dem Suffix Automaton und dem Enhanced Suffix Array, bei der Lösung des Longest Common Substring-Problems in einer reinen Python-Implementierung zu vergleichen.

Die Algorithmen wurden in verschiedenen Szenarien getestet, von besten bis zu schlechtesten Fällen, und auf verschiedenen Stringlängen, von 100 bis 10.000 Zeichen, mit mehreren Durchläufen für jedes Szenario und jede Stringlänge, um die statistische Signifikanz der Ergebnisse sicherzustellen. Sowohl die Aufbauzeit als auch die Abfragezeit wurden gemessen, ebenso wie der für den Aufbau der Datenstruktur und für die Abfrage verwendete Speicher.

*Die Ergebnisse zeigten, dass **solange man in reinem Python programmiert**, ein Enhanced Suffix Array praktisch keine Vorteile gegenüber einem Suffix Automaton bietet. Der Suffix Automaton war wesentlich schneller im Aufbau und in der Abfrage in allen bis auf einer der Szenarien, und obwohl der Enhanced Suffix Array insgesamt eine kleinere Indexgröße hatte, würde dies in realen, speicherbeschränkten Anwendungen nur sehr wenig ausmachen, da sein Spitzen-Speicherverbrauch in allen Szenarien und Stringlängen entweder vergleichbar mit dem des Suffix Automatons oder nur ein wenig kleiner war.*

Dies liegt vermutlich an der Natur von Python, da es eine hochstufige interpretierte Sprache ist, bei der die Speicherverwaltung von der Programmierer/in abstrahiert wird, was dazu führt, dass selbst einfache Datentypen wie Ganzzahlen und Listen einen viel höheren Speicher-Overhead haben als in Sprachen wie C. Aufgrund der Speicherverwaltung von Python würde der Enhanced Suffix Array auch seine Cache-Lokalität verlieren, was der Hauptgrund für seine Kompaktheit in Sprachen wie C ist.

DNA Deoxyribonucleic Acid, the molecule that carries genetic information in living organisms. 1

RNA Ribonucleic Acid, a molecule that is transcribed from DNA and which then gets translated into proteins. 1

1 Introduction

1.1 Background

The Longest Common Substring (LCS) problem is a fundamental problem in computer science, with applications in multiple domains, bioinformatics being one of the most prominent. This is due to the fact that DNA and RNA sequences are usually encoded as strings for bioinformatics workflows, in a format called FASTA, originally described by Pearson and Lipman in 1985¹.

The LCS problem is defined as follows:

Given two strings S and T, each of length at most n, the longest common substring (LCS) problem is to find a longest substring common to S and T.²

For example, given the strings "AGCTAGC" and "TCTAGCTA", the longest common substring is "CTAGC", which has a length of 5. The LCS problem can be solved using various algorithms, such as dynamic programming, suffix trees, suffix arrays, and suffix automata, each with different time and space complexities.

Of particular interest are the Suffix Automaton (SAM) (also known as Directed Acyclic Word Graph (DAWG)) and the Suffix Array (SA) with Longest Common Prefix (LCP) Array (also known as an Enhanced Suffix Array (ESA)), which both yield the search result in linear time, but differ in their construction time and space requirements.

Both of these data structures are derived from the Suffix Tree, the first linear time and space data structure for solving the LCS problem, which was introduced by Peter Weiner in 1973³ as "bi-trees", although the uncompressed version he introduced is currently referred to as a trie in order to differentiate it from the modern definition of a Suffix Tree, which corresponds to the compressed version as described by McCreight in 1976⁴.

³Weiner 1973.

⁴McCreight 1976.

1.1.1 Suffix Tree

A (compressed) Suffix Tree is constructed from a string S using an algorithm, originally called Algorithm M, mapping a finite string S of characters into an auxiliary index to S in the form of a digital search tree T whose paths are the suffixes of S , and whose terminal nodes correspond uniquely to positions within S^5 .

As the Suffix Automaton and the Enhanced Suffix Array are both further refinements of the Suffix Tree, a Suffix Tree implementation will not be included in the comparisons done in this paper.

1.1.2 Suffix Automaton

A Suffix Automaton (SAM) is a data structure that represents all the substrings of a given string in a compact way.

An efficient and compact data structure for representing a full index of a set of strings is a Suffix Automaton, a minimal deterministic automaton representing the set of all suffixes of a set of strings. Since a substring is a prefix of a suffix, a suffix automaton can be used to determine if a string x is a substring in time linear in its length $O(|x|)$, which is optimal.⁶

The SAM was first introduced by Blumer et al. in 1985⁷, and its use in solving the LCS problem has been explored in various works, such as in the book Text Algorithms by Crochemore and Rytter, in chapter 6⁸.

A notable feature of the Suffix Automaton is that it can be constructed with just one string, and in fact, the same automaton can then be reused to find the Longest Common Substring of that string and any other string, by traversing the automaton with the second string and keeping track of the longest match found.

1.1.3 Enhanced Suffix Array

The generic name *enhanced suffix array* stands for data structures consisting of the suffix array and additional tables.⁹

⁵McCreight 1976.

⁶Mohri, Moreno, and Weinstein 2009.

⁷Blumer et al. 1985.

⁸Crochemore and Rytter 1994.

⁹Abouelhoda, Kurtz, and Ohlebusch 2004.

In this implementation, a Enhanced Suffix Array (ESA) consists of a Suffix Array (SA) and an Longest Common Prefix (LCP) Array, which is all that's necessary to solve the LCS problem in linear time because the LCS can be solved by finding the maximum value in the LCP Array corresponding to suffixes (from the SA) that belong to different strings.

The LCP Array will be constructed using Kasai's algorithm¹⁰, which is a linear time algorithm for constructing the LCP Array from the SA.

1.2 Motivation

Although there have been many papers comparing either the SAM or the ESA to the Suffix Tree, there is a lack of direct comparisons between these two data structures, even though they both solve the same problem using the same underlying principle of representing the suffixes of a string in a compact way.

Moreover, there is a lack of practical comparisons between these two structures in the context of specific programming languages, as the obtuse memory management of languages like Python could potentially lead to real-world results not matching up with theoretical expectations, especially when it comes to space usage.

1.3 Research Question

The primary research question of this paper is:

How do the Suffix Automaton and the Enhanced Suffix Array (ESA) compare in terms of time and space complexity when solving the Longest Common Substring problem in an everyday programming context?

Python¹¹ was chosen as the programming language for this paper due to the fact that it is by far the most popular programming language for bioinformatics¹².

AI Declaration

The usage of AI tools within this project is documented here. I solemnly declare that I have documented all interactions with AI tools, including the prompts used and the outputs received.

System	Prompt	Usage
GitHub Copilot 1	Asked to delete the existing project and provide a simple LaTeX template with a shared preamble, a Chapters subdirectory, TOC, glossary, abbreviations, and Roman numerals for non-content pages.	Template structure and LaTeX setup provided
GitHub Copilot 2	Requested additional title page lines (WAB header, reviewer, module) for the main document.	Title page metadata and layout updated
GitHub Copilot 3	Requested uppercase Roman numerals for front matter and lowercase Roman numerals for back matter page numbering.	Page numbering adjusted in main and exposee
GitHub Copilot 4	Requested exposee title page to include shared info fields (WAB header, department, module, reviewer).	Exposee title page updated to include shared metadata
GitHub Copilot 5	Requested adding the provadis-hochschule.pdf logo to the top right corner of both main and exposee title pages.	Logo added to top right of both title pages
GitHub Copilot 6	Reported that Glossary and Abbreviations sections were missing from compiled output.	Added example \newacronym entries to abbreviations.tex
GitHub Copilot 7	Reported that glossary section still not appearing in final PDF.	Updated settings.tex to include <code>automake</code> option in <code>glossaries</code> package to enable automatic glossary generation

System	Prompt	Usage
GitHub Copilot 8	Requested Python benchmark code for LCS comparison with multiple synthetic scenarios (random strings, implanted mutated substrings, etc.)	Created benchmark script and documentation in Code folder
GitHub Copilot 9	Asked to add a progress-bar-like output.	Added optional single-line in-place progress output with percentage, completed/total steps, elapsed time, ETA, and <code>-progress/-no-progress</code> flags
GitHub Copilot 10	Reported that ETA was inaccurate due to varying string lengths	Reworked ETA estimation to be algorithm- and length-aware using observed per-bucket runtimes
GitHub Copilot 11	Requested separate build and query timing (and plots).	Refactored benchmark to record build/query time separately and added total time summaries
GitHub Copilot 12	Requested plots using statistics beyond the mean (median, standard deviation, etc.).	Expanded summary stats and generated mean+std and median+IQR plots alongside memory plots
GitHub Copilot 13	Requested splitting benchmarking and plotting so plot generation can run separately, with a shared CLI entry point and default run-then-plot behavior.	Added CLI mode switch (run/plot/both) to reuse saved CSV results for plotting without rerunning benchmarks
GitHub Copilot 14	Requested an error if the two algorithms return different LCS result strings for the same input.	Added strict substring equality check (in addition to length) and raise an error on mismatch
GitHub Copilot 15	Requested that, in case of multiple valid LCS results, both algorithms return all results and compare the sets.	Updated both algorithms to return all max-length substrings and compare result sets for correctness
GitHub Copilot 16	Requested refactoring the benchmark script into helper modules under a helpers subdirectory, with separate algorithm imports and plotting helper, and clean top-level imports in the main file.	Split benchmark code into dedicated helper modules (SAM, ESA, plotting, generation, statistics, benchmarking) and simplified main script orchestration
GitHub Copilot 17	Requested mean, median, standard deviation, and IQR for memory usage plots as well.	Added memory quartile aggregation and generated memory mean+SD plus median+IQR plots
GitHub Copilot 18	Asked for a practical memory/space-complexity metric and whether build-time and query-time memory can be measured separately.	Added separate build/query phase memory metrics and a persistent index-size metric, with aggregation and plots for comparison

System	Prompt	Usage
GitHub Copilot 19	Asked whether adding total time (build + query) columns and graphs with full statistics would make sense.	Added full total-time statistics (mean, median, std, IQR, Q1, Q3) to summaries and created dedicated total-time plots
GitHub Copilot 20	Requested moving plot legends away from the top center because they obscured titles.	Repositioned all figure legends to the right side outside the plotting area to keep titles unobstructed
GitHub Copilot 21	Requested an additional output file containing both generated strings and their LCS value(s).	Added export of one CSV per generated case with ‘s’, ‘t’, LCS length, and all LCS substrings
GitHub Copilot 22	Asked to replace the lambda with a tuple-key-based approach.	Replaced lambda-based sorting with a tuple-key-based approach for suffix array construction, improving performance
GitHub Copilot 23	Asked to refactor the plotting code to reduce repetition and make it more modular.	Refactored plotting code to use a single generic plotting function
GitHub Copilot 24	Asked to replace the suffix array construction with the SA-IS algorithm.	Replaced doubling-based suffix array construction with an SA-IS implementation (linear-time induced sorting with LMS recursion), keeping the same public API
